

CMPE 200
Computer Architecture & Design

Lecture 1.
**Computer Architecture &
Design Overview (2)**

Haonan Wang

SAN JOSÉ STATE
UNIVERSITY

About Prerequisite – What to Submit?

- **If you have 180D in your admission letter (conditionally classified)**
 - You then need to **submit your transcript with 180D highlighted**
 - You cannot take this course before finishing 180D
- **If you do not have 180D in your admission letter**
 - You then need to **submit your admission letter**
- **If you are admitted with classified standing in your admission letter**
 - You then need to **submit your admission letter**

Relative Performance

- Define Performance = 1/Execution Time
- “X is n times faster than Y”

$$\begin{aligned} & \text{Performance}_X / \text{Performance}_Y \\ &= \text{Execution time}_Y / \text{Execution time}_X = n \end{aligned}$$

Example: time taken to run a program -- 10s on a computer A, 15s on computer B

$$\text{Execution Time}_B / \text{Execution Time}_A = 15\text{s} / 10\text{s} = 1.5$$

A is 1.5 times faster than B.

Measuring Execution Time

- **Elapsed time**
 - Total response time, including all aspects
 - Processing, I/O, OS overhead, idle time
 - Determines system performance
- **CPU time**
 - Time spent processing a given job on CPU
 - Discounts I/O time, other jobs' shares
 - Estimating CPU time is relatively easy based on the number of lines of code and processing speed of the CPU

CPU Clocking

- Operation of digital hardware governed by a constant-rate clock
- Different system components may have different clock rates

Clock period: duration of a clock cycle

e.g., $250\text{ps} = 0.25\text{ns} = 250 \times 10^{-12}\text{s}$

Clock frequency (rate): cycles per second

e.g., $4.0\text{GHz} = 4000\text{MHz} = 4.0 \times 10^9\text{Hz}$

CPU Time Estimation

- A code line of high-level language program can be translated to **one or multiple** assembly code lines
- CPU processes a piece of machine code for each assembly code line, one by one
- **Example:** Application A has 1000 assembly lines. CPU has 250 ps clock period.

Clock cycles for Application A

= 1000 cycles

CPU time for Application A

= 1000 cycles x 250 ps = 250×10^{-9} s

High-level
language
program
(in C)

```
swap(int v[], int k)
{int temp;
  temp = v[k];
  v[k] = v[k+1];
  v[k+1] = temp;
}
```

Compiler

Assembly
language
program
(for MIPS)

```
swap:
    muli $2, $5, 4
    add  $2, $4, $2
    lw   $15, 0($2)
    lw   $16, 4($2)
    sw   $16, 0($2)
    sw   $15, 4($2)
    jr   $31
```

Assembler

Binary machine
language
program
(for MIPS)

```
000000001010000100000000000011000
000000000000110000001100000100001
100011000110001000000000000000000
100011001111001000000000000000100
101011001111001000000000000000000
101011000110001000000000000000100
00000011111000000000000000001000
```

CPU Time

$$\begin{aligned}\text{CPU Time} &= \text{Clock Cycles} \times \text{Clock Period} \\ &= \text{Clock Cycles} / \text{Clock Frequency}\end{aligned}$$

CPU Time Example

- **Computer A:** 2GHz clock, 10s CPU time to run an Application
- **Designing Computer B**
 - Aim for 6s CPU time for the same Application
 - Can do faster clock, but causes $1.2 \times$ clock cycles
- **How fast must Computer B clock be?**

$$\begin{aligned}\text{CPU Time}_B &= 6 \text{ seconds} \\ &= \text{Clock Cycles}_B \times \text{Clock Period}_B \\ &= 1.2 \times \text{Clock Cycles}_A \times \text{Clock Period}_B \\ &= 1.2 \times 20 \times 10^9 \times \text{Clock Period}_B\end{aligned}$$

$$\begin{aligned}\text{Therefore, Clock Period}_B &= 6 \text{ second} / (24 \times 10^9) \\ \text{Clock Frequency}_B &= 4 \times 10^9 = 4\text{GHz}\end{aligned}$$

$$\begin{aligned}\text{CPU Time}_A &= \text{Clock Cycles}_A / \text{Clock Frequency}_A \\ 10 \text{ seconds} &= \text{Clock Cycles}_A / 2\text{GHz} \\ \text{Clock Cycles}_A &= 10 \text{ seconds} \times 2\text{GHz} = 20 \times 10^9 \text{ cycles}\end{aligned}$$

Instruction Count and CPI

- An assembly line is also called one **Instruction**
- In some CPUs, an instruction may take **multiple clock cycles**
- **CPU Time equation can be rewritten**

CPU Time

= Clock Cycles x Clock Period

= Instruction Count x Cycles Per Instruction x Clock Period

- **Cycles Per Instruction** is also called **CPI**

High-level
language
program
(in C)

```
swap(int v[], int k)
{int temp;
  temp = v[k];
  v[k] = v[k+1];
  v[k+1] = temp;
}
```

Compiler

Assembly
language
program
(for MIPS)

```
swap:
    muli $2, $5, 4
    add  $2, $4, $2
    lw   $15, 0($2)
    lw   $16, 4($2)
    sw   $16, 0($2)
    sw   $15, 4($2)
    jr   $31
```

Assembler

Binary machine
language
program
(for MIPS)

```
000000001010000100000000000011000
000000000000110000001100000100001
100011000110001000000000000000000
100011001111001000000000000000100
101011001111001000000000000000000
101011000110001000000000000000100
00000011111000000000000000001000
```

CPI Example

- A program takes 33 billion instructions to run
- CPU processes instructions at 2 cycles per instruction
- Clock speed is 3GHz

What is estimated CPU Time for this program?

$$\begin{aligned}\text{CPU Time} &= \text{Instruction Count} \times \text{CPI} \times \text{Clock Period} \\ &= 33 \times 10^9 \times 2 \times 1/(3 \times 10^9) \\ &= 22 \text{ seconds}\end{aligned}$$

CPI Example

- **Computer A:** Cycle Period = 250ps, CPI = 2.0
- **Computer B:** Cycle Period = 500ps, CPI = 1.2
- **Same number of instructions**

Which is faster, and by how much?

$$\begin{aligned}\text{CPU Time}_A &= \text{Instruction Count} \times \text{CPI}_A \times \text{Clock Period}_A \\ &= \text{Instruction Count} \times 2.0 \times 250 \text{ ps} \\ &= \text{Instruction Count} \times 500 \text{ ps}\end{aligned}$$

$$\begin{aligned}\text{CPU Time}_B &= \text{Instruction Count} \times \text{CPI}_B \times \text{Clock Period}_B \\ &= \text{Instruction Count} \times 1.2 \times 500 \text{ ps} \\ &= \text{Instruction Count} \times 600 \text{ ps}\end{aligned}$$

Computer A is faster than B by $600\text{ps}/500\text{ps} = 1.2$ times

CPI and Average CPI

- In some CPUs, different types of instructions (i.e. integer instruction vs. floating point instruction) may take different number of cycles

- CPU Time equation can be rewritten

$$\begin{aligned}\text{CPU Time} &= \text{Clock Cycles} \times \text{Clock Period} \\ &= \sum [IC_i \times CPI_i] \times \text{Clock Period}\end{aligned}$$

- Average CPI

= Total Clock Cycles / Total IC

= $\sum [IC_i \times CPI_i] / \text{Total IC}$

Sum of (IC of each type instruction x CPI of the type)
(IC = instruction count)

High-level
language
program
(in C)

```
swap(int v[], int k)
{
    int temp;
    temp = v[k];
    v[k] = v[k+1];
    v[k+1] = temp;
}
```

Compiler

Assembly
language
program
(for MIPS)

```
swap:
    muli $2, $5, 4
    add  $2, $4, $2
    lw   $15, 0($2)
    lw   $16, 4($2)
    sw   $16, 0($2)
    sw   $15, 4($2)
    jr   $31
```

Assembler

Machine
language
program
(for MIPS)

```
000000001010000100000000000011000
000000000000110000001100000100001
100011000110001000000000000000000
100011001111001000000000000000100
101011001111001000000000000000000
101011000110001000000000000000100
00000011111000000000000000001000
```

Example: Average CPI

Instruction Type	Integer	Floating point	Branch	Load/Store
CPI for type	1	2	4	3
Instruction Count in program A	50	10	10	10
Instruction Count in program B	20	0	10	10

- Program A: Total Instructions = 80

$$\text{Clock Cycles} = 50 \times 1 + 10 \times 2 + 10 \times 4 + 10 \times 3 = 140$$

$$\text{Avg. CPI} = 140/80 = 1.75$$

$$\begin{aligned} \text{CPU time (if Clock period} &= 100 \text{ ps)} \\ &= 1.75 \times 80 \times 100 \text{ ps} = 14000 \text{ ps} = 14 \text{ ns} \end{aligned}$$

- Program B: Total Instructions = 40

$$\text{Clock Cycles} = 20 \times 1 + 10 \times 4 + 10 \times 3 = 90$$

$$\text{Avg. CPI} = 90/40 = 2.25$$

$$\begin{aligned} \text{CPU time (if Clock period} &= 100 \text{ ps)} \\ &= 2.25 \times 40 \times 100 \text{ ps} = 9000 \text{ ps} = 9 \text{ ns} \end{aligned}$$

Power and Performance

In CMOS IC technology

$$\text{Power} = \text{Capacitive load} \times \text{Voltage}^2 \times \text{Frequency}$$

Issue with Power Scaling

- **Increasing core frequency may burn your processor!**

- Almost all energy consumption turns into heat

- **Cooling is costly**

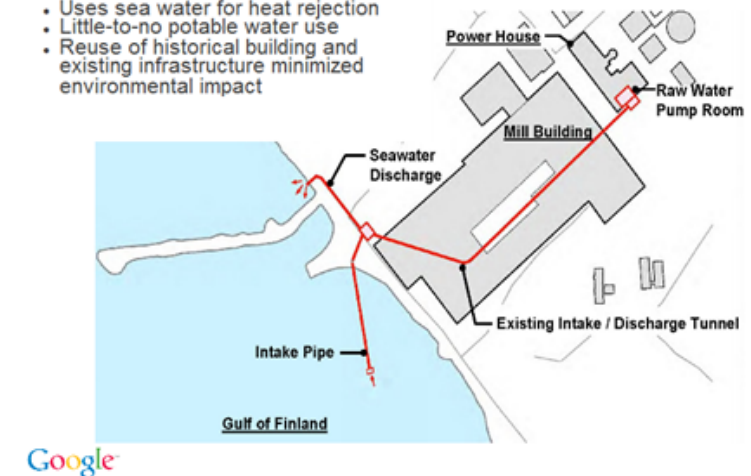

- **Design more efficient system instead**

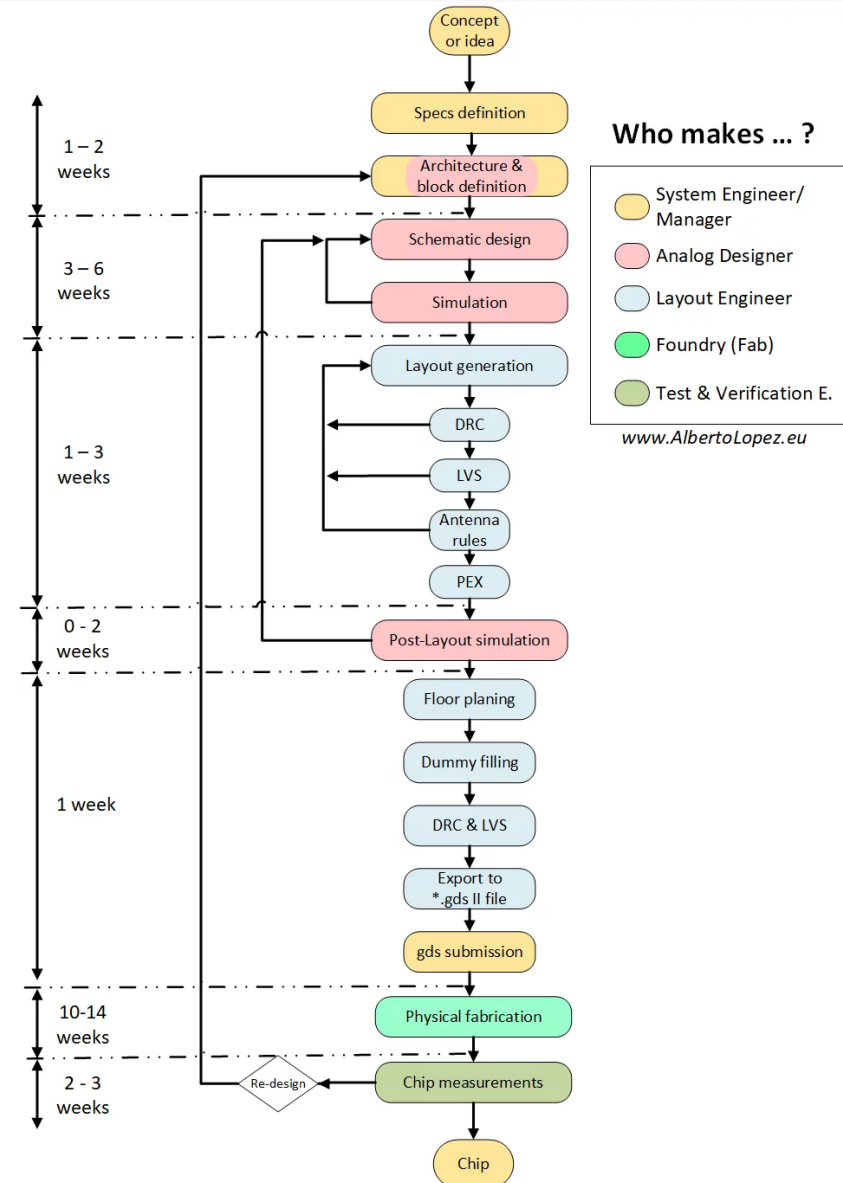

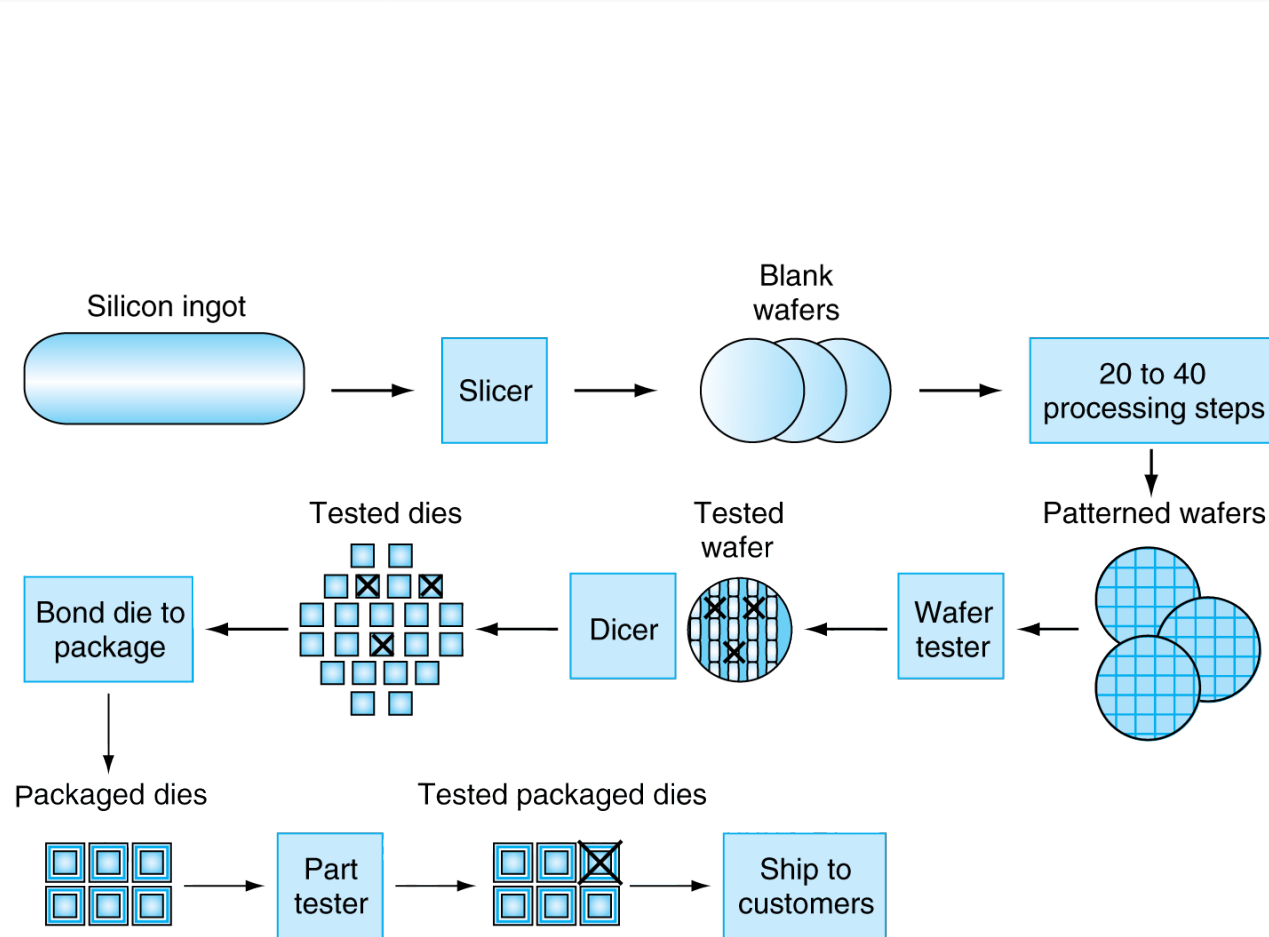

- Multicore, etc..

Sea Water Use

- Uses sea water for heat rejection
- Little-to-no potable water use
- Reuse of historical building and existing infrastructure minimized environmental impact

Design and Manufacturing Process

Course Modules

- **ISA**
- **Processor**
- **Memory**
- **Multicore**

Conclusion Time

What is average CPI?

- $\sum IC_i \times CPI_i / \text{Total IC}$

What is wrong with increasing power to the system?

- Heat
- Cost
